

...But It Also Brings Death

The Cyptians possess an organ called a Memori. Its function involves sucking in water molecules from the atmosphere, bringing them into the thermal atrium where they are boiled into steam and then sent through veins into the main brain. This organ's collective feature aids in their long term memory process, but presents some serious health risks.

The molds in the environment may be rich in ethane, but they also produce toxic chemicals that float into the atmosphere and contaminate the cave walls.

These toxins have the ability to travel into the Memori just like the water molecules. They then drip into the thermal atrium and do damage to the fleshy lining of the organ. When the thermal atrium becomes too thin from corrosion, it breaks open and the toxins react with the CBB hormones and create an interior combustion so large it releases a heavy shock throughout the Cyptian's body and they die.
